### Summary

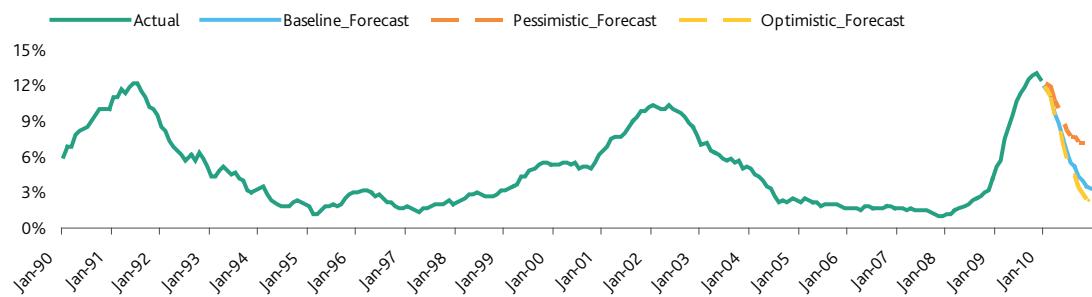

This report comprises Moody's twenty-third annual default study in which we update statistics on the default, loss, and rating transition experience of corporate bond and loan issuers for 2009, as well as for the historical period since 1920. Briefly, we find that:

- » 261 Moody's-rated corporate issuers defaulted on a total of \$183.3 billion of bonds and \$145.5 billion of loans in 2009. Including issuers whose ratings were withdrawn prior to January 1, 2009, 265 corporate issuers defaulted on \$183.3 billion of bonds and \$146.5 billion of loans.
- » In contrast to 2008, when default volume was boosted by several large bank failures, non-financial corporate issuers drove default volumes in 2009, accounting for 74.8% of total volume versus only 20.6% of volume in 2008.
- » Across regions, 200 of 2009's defaulters were North American issuers (191 in the U.S. and 9 in Canada) with defaulted debt volumes totaling \$291.0 billion. In Europe, 30 Moody's-rated corporate issuers defaulted on \$15.5 billion of debt. The remaining defaulters were Latin-American and Asian issuers.
- » Moody's global speculative-grade default rate ended 2009 at 13.0%, almost tripling 2008's year-end level of 4.4%. This compares favorably with our one-year ago forecast of 15.1%. The default rate for all Moody's-rated corporate issuers rose to 5.4% at the end of 2009 from 2.0% at year-end 2008.
- » Measured on a dollar volume basis, Moody's global speculative-grade bond default rate ended 2009 at 15.6%, up from 5.9% at the end of 2008. Among all Moody's-rated issuers, the volume-weighted default rate increased to 2.6% in 2009 from 2.2% in 2008.
- » Moody's global speculative-grade default rate forecasting model now predicts that the speculative-grade default rate will fall sharply to 3.3% by the fourth quarter of 2010. This baseline scenario assumes an ongoing economic recovery and stable credit spreads through 2010. Under a more pessimistic scenario, in which the economic recovery falters and spreads move higher, the default rate is forecast to decline to 7.0% by the end of 2010.

- » The quarterly downgrade-to-upgrade ratio climbed to 18.3 in the first quarter of 2009, the highest quarterly level in over 27 years. The ratio then fell sharply over the remainder of the year and reached 1.8 in the fourth quarter.
- » Measured by post-default trading prices, the average recovery rate for senior unsecured bonds rose to 37.7% in 2009 from 33.8% in 2008. The increase was triggered by higher recovery rates for distressed exchanges. Excluding distressed exchanges, the average senior unsecured bond recovery rate in 2009 was 25.4%.

---

#### Global Speculative-Grade Default Rate Forecast

## Introduction

Moody's credit ratings facilitate the efficient functioning of capital markets by providing independent opinions on the creditworthiness of debt obligations issued by corporate issuers around the world. One of the primary purposes of Moody's corporate default study is to communicate the historical performance of Moody's ratings as predictors of default and loss severity for corporate issuers. In addition to providing useful data for investors and regulators, Moody's default studies also contribute to the transparency of the rating process and directly address the meaning of Moody's long-term debt ratings scale.

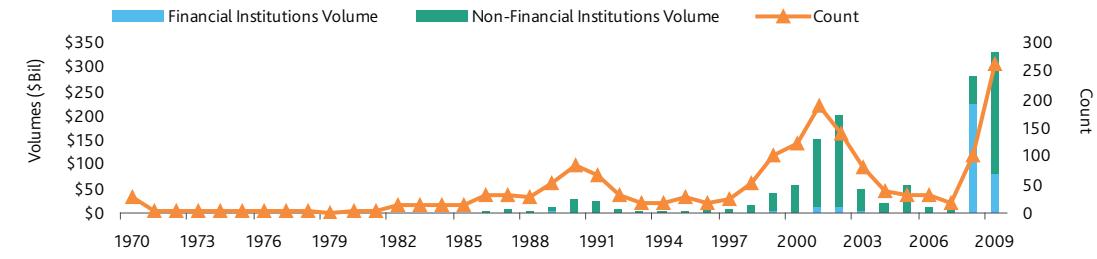

In this study, we first summarize corporate default experience and credit trends in 2009 and then discuss Moody's forecast for speculative-grade corporate default rates in 2010. This is followed by a review of 2009 rating accuracy metrics and the historical statistics on corporate defaults, ratings transitions, ratings performance metrics, and recovery rates. This year's default study includes several revisions to the historical data relative to previous years' reports, which are described in detail in a separate section at the end of the study. Finally, this report also includes several detailed sections describing the methodologies used to generate the statistics as well as a guide to their reading and interpretation.

## 2009 – A Record Year for Defaults

Both default counts and defaulted debt volumes reached record highs in 2009. In contrast to 2008, when the global financial crisis resulted in defaults by a number of large banks and financial institutions, non-financial corporate issuers were the main driver of default volumes in 2009. In fact, non-financial companies accounted for 74.8% of volume in 2009, compared to 20.6% in 2008. Measured by default counts, however, non-financial companies accounted for 87.4% of defaults in 2009, up modestly from 81.4% in 2008.

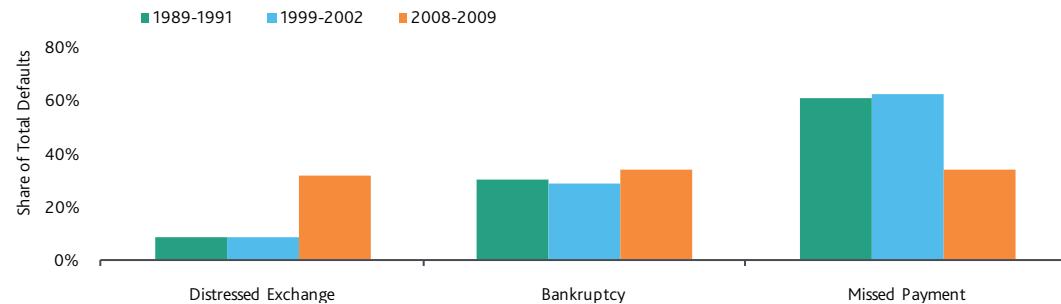

World-wide, 261 Moody's-rated corporate issuers defaulted on a total of \$328.9 billion of debt in 2009. Default counts and volumes both surged from their 2008 levels when only 102 companies defaulted on \$280.6 billion of debt. From a geographic standpoint, 200 of the 261 defaulters were based in North America, while 30 were based in Europe. On a volume basis, defaulted debt totaled \$291.0 billion in North America and \$15.5 billion in Europe. Exhibit 1 presents annual default counts and defaulted debt volumes for the period 1970 to 2009, showing the unprecedented impact that the global economic recession has had on the default environment during the past two years.

**EXHIBIT 1**  
**Default Counts and Volumes Soar in 2008-2009**

Distressed exchanges have played a prominent role in driving default counts higher during the past two years, accounting for 34.9% of total initial defaults in 2009 and 23.5% in 2008 (see Exhibit 2). To put this in context, distressed exchanges accounted for only approximately 11.0% of initial defaults during the period 1983 through 2007. In the fourth quarter of 2008 and the first half of 2009, several factors especially accelerated the pace of distressed exchanges, including the inability of many speculative-grade issuers to access the debt markets and the unattractiveness of bankruptcy given the lack of DIP and exit financing.

## EXHIBIT 2

**Distressed Exchanges Spike in 2008-2009 Relative to Previous Cycles**

Among the 261 defaulters in 2009, more than a third of them were by issuers in the Capital Industries sectors.<sup>1</sup> Within this sector, defaults were highest in the automotive industry. Issuers in the Capital Industries sector also accounted for a 40.8% share of total default volume in 2009. Issuers in the FIRE sector<sup>2</sup> accounted for the next highest share of 2009 default volume with a 20.2% share of total volume. By broad industries, Exhibit 3 shows 2009 total default counts and debt volume shares.

## EXHIBIT 3

**2009 Defaults by Broad Industry**

BROAD INDUSTRY	PERCENT OF ISSUER COUNTS	PERCENT OF DOLLAR VOLUME
Banking	5.7%	5.0%
Capital Industries	36.4%	40.8%
Consumer Industries	18.0%	8.0%
Energy & Environment	2.7%	0.8%
FIRE	6.9%	20.2%
Media & Publishing	16.5%	17.5%
Retail & Distribution	2.3%	0.5%
Technology	8.4%	6.6%
Transportation	2.7%	0.5%
Utilities	0.4%	0.0%
Total	261	\$328.9 billion

<sup>1</sup> Capital industries sector includes automotive, capital equipment, chemicals, plastics, & rubber, construction & building, containers, packaging, & glass, forest products & paper, metals & mining, and business service industries. Consumer industries sector includes beverage, food, & tobacco, durable and non-durable consumer goods, healthcare & pharmaceuticals, hotel, gaming, & leisure, and consumer service industries.

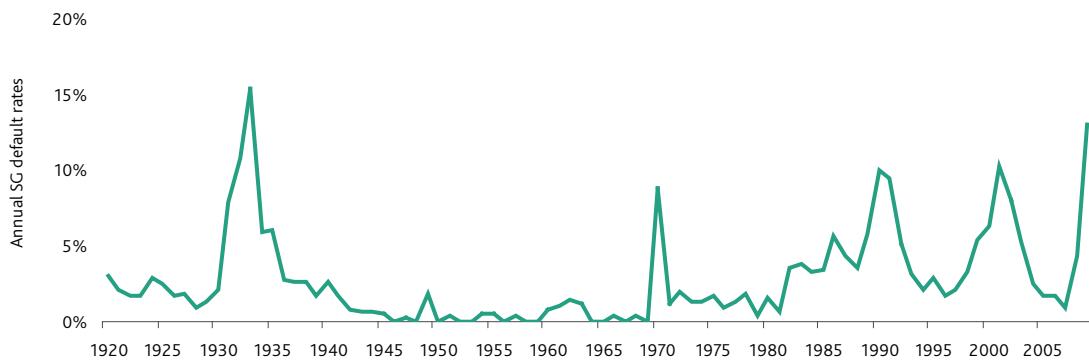

<sup>2</sup> FIRE sector includes Finance, Insurance, and Real Estate industries.

Exhibit 4 lists the largest 2009 defaults measured by default volume. Not surprisingly, four of the defaults were by companies in the Capital Industries, with three of those in the automobile industry, including General Motors, Ford, and Chrysler. While General Motors was the largest default at \$47.8 billion in debt, CIT Group was a close second at \$42.3 billion.

**EXHIBIT 4****Largest 2009 Defaults**

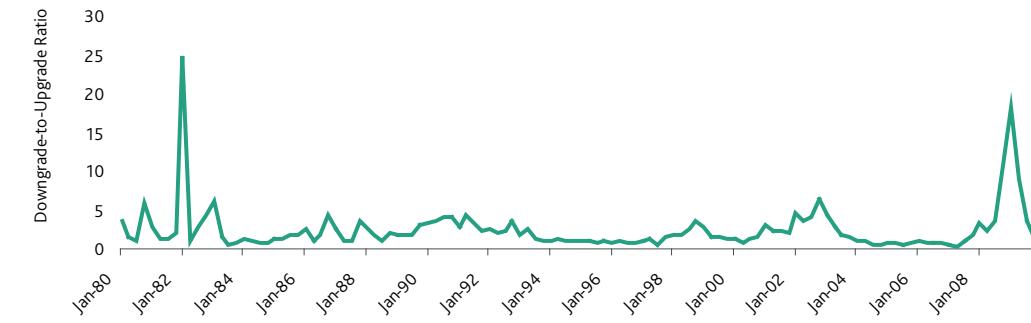

COMPANY	BROAD INDUSTRY	SPECIFIC INDUSTRY	VOLUME (BIL)
General Motors Corporation	Capital Industries	Automotive	\$47.8
CIT Group Inc.	FIRE	FIRE: Finance	\$42.3
Lyondell Chemical Company	Capital Industries	Chemicals, Plastics, & Rubber	\$19.2
Charter Communications Operating LLC	Media & Publishing	Media: Broadcasting & Subscription	\$10.8
Ford Motor Company	Capital Industries	Automotive	\$9.8
Idearc, Inc.	Media & Publishing	Media: Advertising/Printing/Publishing	\$9.4
Chrysler LLC	Capital Industries	Automotive	\$9.0
Capmark Financial Group Inc.	FIRE	FIRE: Real Estate	\$8.7
BTA Bank	Banking	Banking	\$4.8
Harrah's Operating Company, Inc.	Consumer Industries	Hotel, Gaming, & Leisure	\$4.6

As a result of rapidly increasing defaults in 2009, the trailing twelve-month issuer-weighted default rate for all Moody's-rated issuers jumped to 5.4% in 2009 from 2.0% in 2008. Among speculative-grade issuers, the default rate rose to 13.0% in 2009, almost triple its closing level of 4.4% at the end of 2008 and in close agreement with Moody's forecast of 15.1%. The 2009 year-end speculative-grade default rate exceeded the annual peaks of 10.3% and 10.0% set in 2001 and 1990, respectively, but failed to surpass the peak of 15.4% set during the Great Depression (see Exhibit 5). Measured on a dollar volume basis, Moody's speculative-grade corporate bond default rate jumped to 15.6% in 2009 from 5.9% in 2008. The volume-weighted default rate for all Moody's-rated issuers increased to 2.6% in 2009 from 2.2% in 2008.

**EXHIBIT 5****Global Speculative-Grade Default Rate Reaches Post-War High**

Consistent with rapidly weakening credit quality and increasing numbers of defaults, the quarterly downgrade-to-upgrade ratio for corporate issuers began rising sharply in late 2008,<sup>3</sup> reaching a peak of 18.3x in the first quarter of 2009. During the remainder of 2009, however, the downgrade-to-upgrade ratio declined steeply and reached 1.8x in the fourth quarter, approximately the same level as just prior to the start of the recession in the fourth quarter of 2007. For historical perspective, Exhibit 6 shows the quarterly downgrade-to-upgrade ratio for Moody's-rated corporate issuers since 1980.

**EXHIBIT 6**  
**Quarterly Downgrade-to-Upgrade Ratio Declined Sharply in Second Half of 2009**

Historically, as shown by Moody's research<sup>4</sup>, default rates and recovery rates are negatively correlated. In 2009, with default rates increasing sharply, this relationship manifested itself again as loan recovery rates were significantly below their long-run historical averages as shown in Exhibit 7. However, on the bond side, this relationship was not as readily apparent as holders of senior unsecured and subordinated bonds enjoyed above-average recovery rates in 2009. The explanation for this anomaly is the large share of defaults accounted for by distressed exchanges—which have significantly higher average recovery rates than those associated with bankruptcies and missed payments.

**EXHIBIT 7**  
**Average Corporate Debt Recovery Rates Measured by Post-Default Trading Prices**

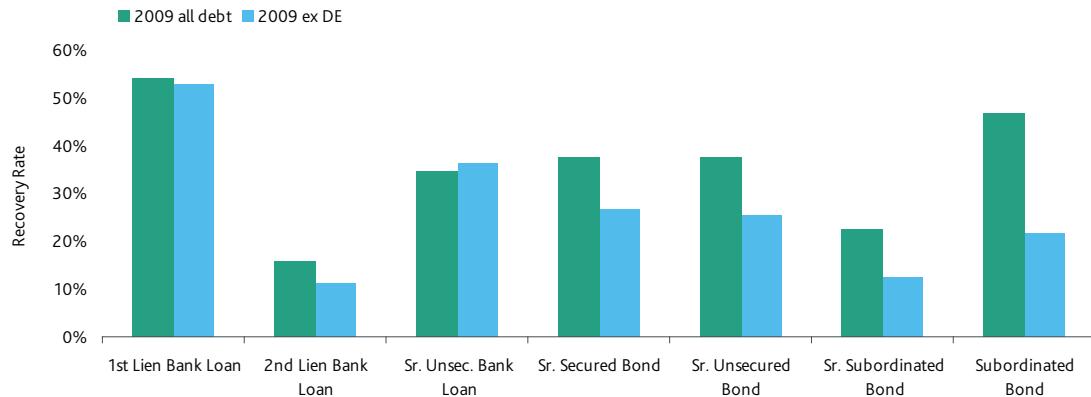

LIEN POSITION	ISSUER-WEIGHTED			VALUE-WEIGHTED		
	2009	2008	1982-2009	2009	2008	1982-2009
1st Lien Bank Loan	54.0%	61.7%	65.6%	56.6%	46.9%	59.1%
2nd Lien Bank Loan	16.0%	40.4%	32.8%	20.5%	36.6%	1.9%
Sr. Unsecured Bank Loan	34.5%	31.6%	48.7%	38.1%	22.8%	40.0%
Sr. Secured Bond	37.5%	54.9%	49.8%	29.5%	40.3%	48.5%
Sr. Unsecured Bond	37.7%	33.8%	36.6%	35.5%	26.2%	32.6%
Sr. Subordinated Bond	22.4%	23.7%	30.7%	17.9%	10.4%	25.0%
Subordinated Bond	46.8%	23.6%	31.3%	24.7%	7.3%	23.5%
Jr. Subordinated Bond	n.a.	n.a.	24.7%	n.a.	n.a.	17.1%

<sup>3</sup> These data are not adjusted for the impact of methodology changes (e.g. JDA, LGD). As a result, the data are not comparable to the downgrade/upgrade ratios shown in Moody's Quarterly Rating Action reports.

<sup>4</sup> See Moody's Special Comment "[Corporate Default and Recovery Rates, 1920-2006](#)", Feb 2007

Exhibit 8 shows the impact that distressed exchanges had on boosting 2009 recovery rates across debt types. Since a large majority of distressed exchanges involve only junior debt, first lien loan recovery rates were barely affected by distressed exchanges, while the impact was more substantial for unsecured and subordinated bonds. For example, excluding distressed exchange defaults, the 2009 average subordinated bond recovery rate would have been 21.8%, which is 50% lower than the 46.8% recovery that includes distressed exchanges.

**EXHIBIT 8**  
**Distressed Exchanges Boosted 2009 Bond Recovery Rates**

The recovery data discussed above are based on debt trading prices 30 days after the default date. An alternative recovery measure is based on ultimate recoveries, or the value creditors realize at the resolution of a default event. For example, for issuers filing for bankruptcy, the ultimate recovery is the present value of the cash and/or securities that the creditors actually receive when the issuer exits bankruptcy, typically 1-2 years following the initial default date.<sup>5</sup>

In Exhibit 9, we present data on ultimate recovery rates for North American companies included in Moody's Ultimate Recovery Database.<sup>6</sup> In 2009, Moody's added 11 firms that either emerged from bankruptcy or resolved their default events. The average "firm-wide" recovery rate<sup>7</sup> for these 11 firms was 45.4%, below 2008's 57.3% level, and the long-term average of 53.3% since 1987. As shown in Exhibit 9, the individual debts at these 11 firms experienced lower average recoveries in 2009 compared to average recoveries in 2008. For example, senior unsecured bonds recovered an average 9.6% in 2009, only 15% of the comparable figure for 2008.

<sup>5</sup> For details, see Moody's Special Comment "[Moody's Ultimate Recovery Database](#)," April 2007.

<sup>6</sup> The data is from Moody's Ultimate Recovery Database which includes robust detailed recovery information for over 3500 loans and bonds from more than 700 U.S. corporate defaulters since 1987.

<sup>7</sup> For a given issuer, the firm-wide recovery rate is the weighted-average recovery rate across all of the issuer's debts where the weights are the size of the debts relative to total debt. Or in other words, it is the enterprise value of the issuer divided by the firm's total debts at the time of resolution.

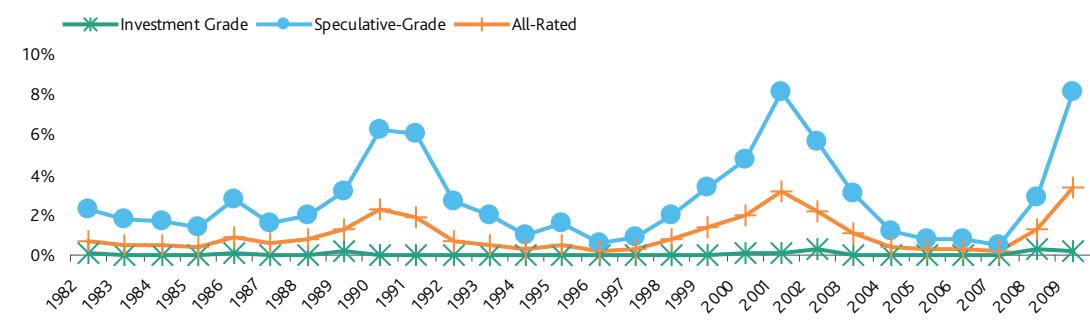

## EXHIBIT 9

**Average Corporate Debt Recovery Rates Measured by Ultimate Recoveries, 1987-2009**

LIEN POSITION	EMERGENCE YEAR			DEFAULT YEAR		
	2009	2008	1987-2009	2009	2008	1987-2009
Loans	74.4%	79.5%	81.1%	88.2%	65.9%	81.1%
<b>Bonds</b>						
Sr. Secured	--	70.0%	66.9%	--	51.1%	66.9%
Sr. Unsecured	9.6%	64.2%	44.6%	11.0%	57.6%	44.6%
Sr. Subordinated	33.2%	39.1%	30.7%	41.5%	34.1%	30.7%
Subordinated	--	--	31.0%	--	--	31.0%
Jr. Subordinated	--	0.0%	21.3%	--	--	21.3%

Moody's credit ratings are opinions of relative expected credit losses, which are a function of both the probability of default and severity of default (LGD). Exhibit 10 shows annual average credit loss rates from 1982 through 2009 for Moody's-rated corporate issuers. In 2009, although bond recovery rates were boosted by a large number of distressed exchanges, the large increase in default rates led to an increase in the average credit loss rate among Moody's-rated issuers to 3.3%, up from 1.3% in 2008. To put this in perspective, the average annual credit loss rate for Moody's-rated issuers since 1982 is 1.0%.

## EXHIBIT 10

**Average Annual Credit Loss Rates, 1982-2009****Default Rate Outlook for 2010**

A year ago, reflecting in large part high yield bonds spreads that were at a level of 2000 basis points, Moody's default rate forecasting model (CTM) predicted that the global speculative-grade default rate would see a three fold increase to 15.1% in 2009, peaking at 15.4% in November. While the realized default rate peaked at a modestly lower level of 13.4%, the model provided advance warning of a rapid climb in the global default rate, correctly predicting in January that the default rate would peak in November, and that the rate would peak at a post-War record high.

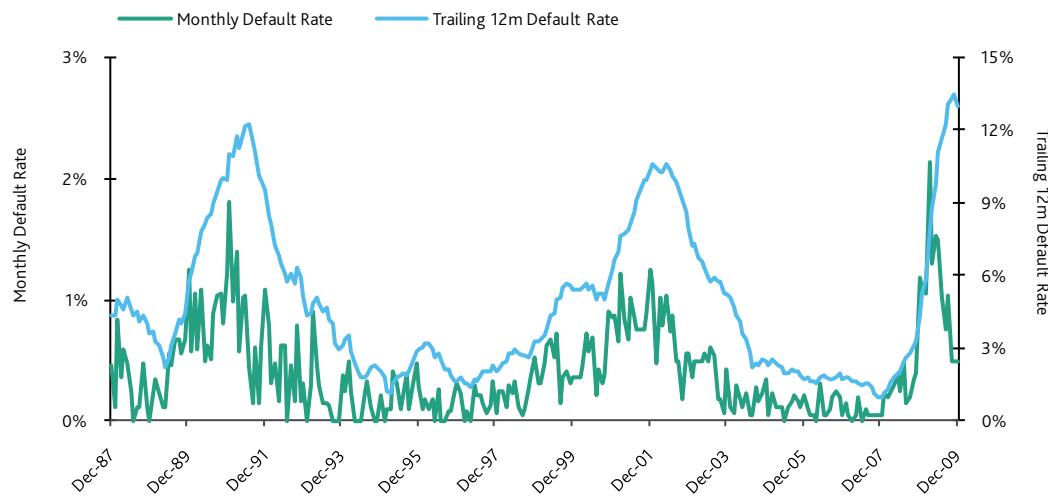

The CTM is now forecasting that the global speculative-grade default rate will fall sharply in 2010, reaching 3.3% by December under the baseline economic scenario. This forecast implies approximately 60 total defaults globally in 2010. The decline in the default rate is expected to be more rapid in the first half of the year with the rate expected to drop to 6.4% by the end of June.

This baseline forecast assumes that the unemployment rate will reach a peak of approximately 10.5% in 2010 and that the high yield spread will decline from its current level of 648 bps to 474 bps by the end of 2010. If the high yield bond spread and unemployment rate, the two macroeconomic factors included in the model, turn out to be higher than these baseline estimates, the global speculative-grade default rate would likely end 2010 above 3.3%. Under a more pessimistic macroeconomic scenario, where the unemployment rate climbs to 14.1% in 2010 and the high yield bond spread increases to 661 basis points, the global speculative-grade default rate is forecasted to decline to 7.2% by the end of 2010.

As shown in Exhibit 11, the forecasted sharp decline in the default rate is consistent with previous credit cycles when the default rate fell sharply shortly after the monthly default rate began to ease. In other words, the trailing twelve-month default rate typically declines once the monthly default count drops off. In 2009, the monthly default count fell off substantially in the second half of the year with the average monthly default count declining to 15.0 from 28.5 in the first half of the year.

---

**EXHIBIT 11**  
**Trailing 12-Month Default Rate Typically Peaks Near Peak in Monthly Default Rate**

For U.S. and European speculative-grade issuers, Moody's forecasting model foresees default rates dropping to 3.6% and 2.7%, respectively, by the end of 2010 under the baseline scenario. Across industries over the coming year, default rates are expected to be highest in the Consumer Transportation sector in the U.S. and the Business Service sector in Europe. Exhibit 12 shows the baseline one-year default rate forecasts across industries in both the U.S. and Europe.

## Rating Accuracy Metrics

Moody's ratings have historically proven to be effective predictors of default. This can be illustrated in Exhibit 13, which plots the average and median ratings of roughly 1,600 corporate issuers that defaulted from 1983 to 2009. The chart shows that Moody's-rated issuers have, on average, been downgraded to the Ba3 level as early as five years prior to default. Among issuers that defaulted in 2009, the average rating was B1 five years prior to default, which is slightly lower than its comparable historical average. In the year prior to default, 2009 defaulters' ratings were downgraded to B3 on average, which is also lower than the long-term average of B2.

## EXHIBIT 13

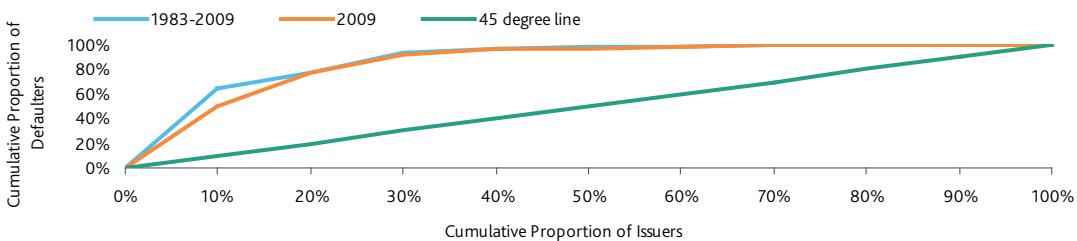

## Average and Median Ratings Prior to Default, 1983-2009

As a valuable tool to measure credit risk, ratings are expected to differentiate strong credits from weaker ones. In other words, an effective rating system should not only assign low ratings to issuers that ultimately default but also assign high ratings to those that are remote to default. A metric designed to measure this aspect of ratings performance is the cumulative accuracy profile (CAP) plot as shown in Exhibit 14. A rating system that possessed no predictive information about default risk would lie on the 45° line; the further the CAP curve bows toward the northwest corner, the greater number of defaults reside in the riskiest rating categories. Exhibit 14 shows that the CAP curve for 2009 lies slightly below the one for the 1983-2009 period, which indicates that the rating performance in 2009 was similar to the historical average.

## EXHIBIT 14

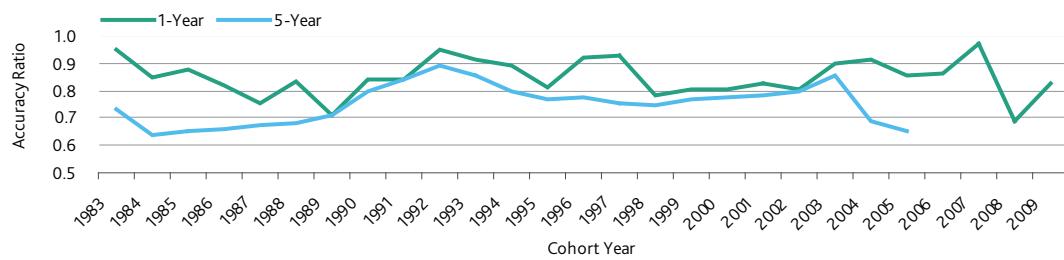

## One Year Cumulative Accuracy Plots, 2009 vs. Historical Average

Another way to measure rating performance is the accuracy ratio, which is derived from the CAP curve. The accuracy ratio (AR) is the ratio of the area between the CAP curve and the 45° line to the maximum possible area above the 45° line, divided by survival rate (i.e. 1-default rate).<sup>8</sup> AR values range from minus one to positive one and a higher AR indicates better rating accuracy. Exhibit 15 shows both one- and five-year horizon accuracy ratios for the period of 1983-2009. The graph suggests that the one-year accuracy ratio is positively correlated with the credit cycle: when defaults increase, the accuracy ratio falls. At the five-year horizon this correlation is much less evident. In the short run, the stability objective of Moody's rating system dampens rating changes; at longer time horizons, the stability objective is less of a constraint, and accuracy increases. In 2009, the one-year accuracy ratio bounced back towards its long-run average following a large decline in 2008, which resulted from several investment-grade financial institution defaults including Lehman Brothers.

## EXHIBIT 15

## 1- and 5-Year Accuracy Ratios by Cohort Year, 1983-2009

<sup>8</sup> In this report, we are calculating Accuracy Ratio as defined in "Benchmarking Quantitative Default Risk Models: A Validation Methodology" (2000). The Accuracy Ratios from prior year reports were defined as the ratio between the CAP curve and the 45 degree line to the maximum possible area above the 45 degree line. In other words, the new AR equals the old AR divided by the survival rate (i.e., 1- default rate) for the cohort under consideration. The adjustment was made for the purpose of allowing Accuracy Ratios to be 100% when defaulters are perfectly differentiated from non-defaulters.

## Guide to Data Tables and Charts

In this section we briefly describe the interpretation of some of the Exhibits contained in this report. Methodological details are discussed in separate sections below.

The chart on the cover page presents Moody's speculative-grade default rate forecast for 2010. The model generated point forecasts for each month are shown, as well as forecasted lower and higher bounds. The pessimistic and optimistic bounds represent positive and negative economic scenarios for the U.S. unemployment rate and high yield spread.

Exhibit 13 was derived by mapping Moody's ratings to a linear scale, then taking the average and median values of the numerically mapped ratings.

Exhibit 22 shows average senior unsecured recovery rates by letter rating and year prior to default. Each cell in the table indicates the average recovery rate on senior unsecured bonds with a specific rating within T years of default. For example, the 35.8% two-year B recovery rate reported in Exhibit 22 indicates that the average recovery rate on B rated issues that default at some time within a two-year period, not mean recovery rate for issuers rated B exactly two years before default.<sup>9</sup> Together with issuer-weighted average cumulative default rates, these multi-period recovery estimates are used to calculate cumulative expected credit loss rates, as presented in Exhibit 23.

Exhibits 33 through 37 show issuer-weighted historical average default rates by rating category over various investment horizons. These data were generated by averaging the multi-year default rates of cohorts formed at monthly intervals. In addition to their being statements of historical fact, these data are also useful proxies for *expected* default rates. For example, over a five-year period a portfolio of B-rated issuers defaulted at a 26.2% average rate between 1983 and 2008 (see Exhibit 35). For an investor with a five-year exposure to a B-rated debt obligation or counterparty, this estimate also happens to be the best estimate of the expected risk of default for a B-rated exposure based on the available historical data, particularly over long investment horizons.

Exhibit 41 shows average cumulative volume-weighted default rates by rating category. Whereas issuer-based default rates weight each issuer equally, these data weight each issuer by the total volume of defaulted debt; larger defaults receive relatively more weight. Average default rates based on debt volume affected are less suitable estimates of expected default risk. One reason is that issuer default volumes vary considerably over time. On average, a leveraged corporate issuer defaults on approximately \$300 million of bonds. However, that total has been as high as \$30 billion (WorldCom). Issuer-based default rates receive particular emphasis in the rating process because the expected likelihood of default of a debt issuer holding a given rating is expected to be the same regardless of differences in the nominal sizes of the exposures.

Exhibit 42 shows the cumulative issuer-weighted historical default rates of cohorts formed at annual intervals between the years 1970 and 2009 (January 1 of each year). These data are a subset of the data used to calculate the issuer-weighted averages shown in Exhibits 34 through 35 (which, again, are based on cohorts formed at monthly time intervals). The default rates in Exhibit 42 may be useful for scenario analysis. For example, if one believed that future default rates for a given pool of issuers will behave as they did in, say, 1997, then one can use the January 1, 1997 cohort cumulative default rates as proxies for expected default rates.

<sup>9</sup> The details of the calculation may be found in Moody's Special Comment, "[Recovery Rates on Defaulted Bonds and Preferred Stocks](#)", December 2003.

## Methodology and Data Sources

### Methodology Changes in Recent Years Report

The historical data contained in Moody's 2010 global default study includes a number of revisions relative to previous years' publications. Moody's occasionally discovers historical defaults, leading to minor revisions of the historical data. As always, the data contained in the most recently published Moody's default study supersedes the data published in previous reports.

#### *Change in Senior Rating Algorithm*

In January 2009, we applied a smoothing procedure in the senior rating algorithm to estimate every issuer's senior unsecured ratings. This enhancement aims at ironing out artificial rating changes that are not resulting from a change in an issuer's credit quality, but due to the switch of reference debt based on which the estimated senior unsecured rating is estimated. The implementation of the smoothing procedure is particularly important to structural breaks when Moody's introduced new debt ratings, refined its rating scale and adjusted its notching practices. For example, the introduction of issuer ratings on October 25 1999 results in numerous artificial rating changes if the smoothing procedure is not in place. During other times, the impact of smoothing is modest. For instance, only 3% of Moody's-rated issuers observe adjustments in their estimated senior unsecured ratings (mostly by one notch) on January 1, 2009.

#### *Removal of Special Purpose Vehicles*

During 2009, we removed a substantial number of special purpose vehicles from our universe of study. These special purpose vehicles were serving purely as financial conduits used for the purposes of issuing debt for other rated operating companies.

#### *Removal of Project Finance Issuers*

In December 2009, we removed approximately 300 past and present project finance issuers from the universe of corporate issuers.

---

## Moody's Definition of Default

Moody's definition of default includes three types of credit events:

1. A missed or delayed disbursement of interest and/or principal at the end of contractual allowed grace period;
2. Bankruptcy, administration, legal receivership, or other legal blocks (perhaps by regulators) to the timely payment of interest and/or principal; or
3. A distressed exchange occurs where: (i) the issuer offers debt holders a new security or package of securities that amount to a diminished financial obligation (such as preferred or common stock, or debt with a lower coupon or par amount, lower seniority, or longer maturity); and (ii) the exchange has the apparent purpose of helping the borrower avoid default.

The definition of a default is intended to capture events that change the relationship between debt holders and the debt issuer from the relationship which was originally contracted, and which subjects the bondholder to an economic loss. Technical defaults (covenant violations, etc.) are not included in Moody's definition of default. Secondary and tertiary defaults are reported only after the initial default event is believed to have been cured. This is to ensure that multiple defaults related to a single episode of credit distress are not over-counted.

### Rating Migration Calculations

A rating migration matrix completely summarizes changes in credit ratings over a given time horizon. The cells of the matrix are discrete-time estimates of rating migration probabilities. They show rate of rating change measured at two points in time; e.g. the start and end of one year. When calculating credit rating migration rates, Moody's treats rating changes, rating withdrawals, and defaults as mutually exclusive states. For example, an issuer that is downgraded on the day of default is counted only as a default, not a downgrade or a downgrade and default. Similarly, an issuer whose rating is withdrawn on the day of default is counted as a default, not a withdrawal.

The probability that an issuer's rating  $i$  held on cohort date  $y$  will transition to rating  $j$  (which includes default and withdrawal) over a time horizon  $T$  is calculated as:

$$p_{ij}^y(T) = \frac{n_{ij}^y(T)}{n_i^y(0)}$$

The weighted average rating migration rate for all cohorts  $y$  in the historical data set  $Y$  is calculated as:

$$\bar{p}_{ij}(T) = \frac{\sum_{y \in Y} n_{ij}^y(T)}{\sum_{y \in Y} n_i^y(0)}$$

### Default Rate Calculation

Moody's method for calculating cumulative default rates is a discrete-time approximation of the nonparametric continuous-time hazard rate approach.<sup>10</sup> Cumulative default rates are calculated from marginal default rates, which represent the probability that an issuer that has survived in the sample through a particular date will default over the next time interval (typically, one year) following that date.

The marginal default rate for issuers holding rating  $i$  on cohort date  $y$  is the ratio of the number of defaulting issuers in period  $t$  divided by the number of issuers exposed to the risk of default in period  $t$ :

$$d_i^y(t) = \frac{x_i^y(t)}{n_i^y(t) - x_i^y(t-1) - \frac{1}{2}[w_i^y(t) + w_i^y(t-1)]}$$

The denominator of the marginal default rate adjusts for defaults that occur prior to time interval  $t$ , as well as rating withdrawals,  $w(t)$ , that occur in periods prior to interval  $t$  and a small adjustment for

<sup>10</sup> See Moody's Global Credit Research "Measuring Corporate Default Rates", November 2006

withdrawals that occur in time interval  $t$ . Cumulative default rates for investment horizons of length  $T$ ,  $D(T)$ , are built up from the marginal default rates:

$$D_i^y(T) = 1 - \prod_{t=1}^T [1 - d_i^y(t)]$$

Or, expanding the above equation (and dropping indices for brevity):

$$D(T) = d(1) + d(2)[1 - d(1)] + d(3)[(1 - d(1))(1 - d(2))] + \dots + d(T)\left(\prod_{t=1}^{T-1} [1 - d(t)]\right)$$

In the first time period, a fraction of the credit exposures in the cohort either defaults or survives. The credit exposures that survive period one may then go on to default or survive in period two; those that survive period two may go on to default or survive in period three, etc. Because the time periods are non-overlapping and the probability of default in each period is assumed to be independent, the  $T$ -period cumulative default rate is defined as one minus the product of the  $T$  marginal survival rates.

The calculation of the average cumulative default rate for rating class  $i$ ,  $\bar{D}_i(T)$ , is derived from the weighted average marginal default rates,  $\bar{d}_i(t)$ , calculated from all the available cohort marginal default rates in the historical data set  $Y$ :

$$\bar{D}_i(T) = 1 - \prod_{t=1}^T [1 - \bar{d}_i(t)]$$

where

$$\bar{d}_i(t) = \frac{\sum_{y \in Y} x_i^y(t)}{\sum_{y \in Y} n_i^y(t)}$$

The default rates calculated in multi-year rating migration matrices are not comparable to those calculated using Moody's discrete-time hazard rate method described above. Rating migration matrices account for rating withdrawals separately (in the column labeled WR) while the hazard rate method incrementally adjusts the denominator of the marginal default rate to remove rating withdrawals. Occasionally, withdrawal-adjusted rating migration matrices are calculated as follows:

$$p_{ij}^y(T)^* = \frac{p_{ij}^y(T)}{(1 - p_{iw}^y(T))}$$

Using this method, *all* issuers whose ratings are withdrawn are removed. In effect, data for issuers whose ratings are withdrawn is completely discarded. This method generally yields higher default rate

estimates than the hazard rate method. Hence, Moody's hazard rate-derived default rate estimates lay between unadjusted migration matrix-derived default rates and withdrawal-adjusted migration matrix-derived default rates.

### Recovery Rate Calculations

Moody's estimates defaulted debt recovery rates using market bid prices observed roughly 30 days after the date of default. Recovery rates are measured as the ratio of price to par value. Using post-default prices to measure recovery (or its complement, loss severity) parallels common practice in the credit default swaps market. Moreover, recovery rates measured in this way are most relevant for cash bond investors who liquidate their holdings shortly after default as often required by their portfolio governance rules or their own investment objectives. For investors holding defaulted securities until ultimate resolution, prices observed shortly after default are generally accepted as the market's estimate of discounted expected ultimate recovery rates.

The alternative approach of directly measuring *ultimate* realized recoveries presents a number of estimation challenges, including the appropriate discount rate to apply to cash-flows and valuing the assets used to pay creditor claims, which may include illiquid new securities (e.g., equity and derivative instruments) as well as physical assets. The table below defines the various ways Moody's calculates recovery rates.<sup>11</sup> For the purposes of measuring expected credit loss rates, we rely on issuer-weighted mean recovery rates.

STATISTIC	DEFINITION
Issuer-Weighted Mean Recovery Rates	They are derived by estimating mean recovery rates for each issuer, then averaging them across issuers. They are useful for predicting recovery rates for portfolios that are well diversified across issuers.
Value-Weighted Mean Recovery Rates	They represent the average of recovery rates on all defaulted issuers, weighted by the face value of those issues. These estimates are useful for predicting recovery rates on the market portfolio.
Issuer-Weighted Median Recovery Rates	They are estimated as median of issuer-weighted recovery rates and are used for predicting the most likely recovery rate for a randomly selected issuer.
Issue-Weighted Mean Recovery Rates	They are estimated using recovery rates for each issue and taking the average of all issues. While this measure is widely reported, it is useful only for predicting the average recovery rate on a portfolio of default bonds diversified across issues but without reference to issuer or issue size.

### Credit Loss Rate Calculations

Moody's credit ratings are opinions of relative expected credit losses. Credit losses are therefore a function of both probability of default (PD) as well as the severity of default (LGD). The expected credit loss rate for rating category  $i$  is calculated as the product of the  $T$ -horizon average issuer-weighted default rate and the  $T$ -horizon average issuer-weighted senior unsecured loss severity rate (where  $r(T)$  is the average senior unsecured recovery rate at horizon  $T$ ):

$$l_i(T) = \bar{D}_i(T) \times (1 - \bar{r}_i(T))$$

<sup>11</sup> This table is derived from Moody's Special Comment "[Recovery Rates on Defaulted Bonds and Preferred Stocks](#)", December 2003

## CaP Curve and Accuracy Ratio

In addition to assigning low ratings to issuers that ultimately default, the effectiveness of a rating system depends on its ability to assign high credit ratings to issuers that do not default. In other words, an efficient rating system is able to separate the low credit risks from the high credit risks. A metric designed to measure this aspect of ratings performance is the cumulative accuracy profile (CaP) plot.<sup>12</sup> The CaP plot graphs the cumulative proportion of defaults from a portfolio (the y-axis) against the proportion of issuers exposed to the risk of default (the x-axis), sorted by riskiness. A rating system that randomly identified defaults from non-defaults would plot a line directly on the 45-degree line. The more powerful the discriminatory power of the rating system, the further the CaP curve bows toward the top left corner.

CaP curves are powerful tools for visualizing rating performance, but can be unwieldy from making comparisons over many time periods. A summary measure of rating accuracy that can be derived from the CaP curve is the accuracy ratio (AR). The accuracy ratio is the ratio of the area between the CaP curve and the 45-degree line to the total area above the 45-degree line, divided by survival rate (i.e. 1-default rate). A rating system that perfectly differentiates defaults from non-defaults would score an AR of 100%, while a rating system that had zero predictive ability would score 50%.<sup>13</sup>

## Data Sources

Moody's bases the results of this study on its proprietary database of ratings and defaults for corporate bond and loan issuers. Municipal and sub-sovereign debt issuers, structured finance securities, private placements, and issuers with only short-term debt ratings are excluded unless otherwise noted. In total, Moody's data covers the credit experiences of over 18,000 corporate issuers that sold long-term public debt at some time between 1920 and 2009. As of January 1, 2009 approximately 5,000 corporate issuers held a Moody's long-term bond, loan, or corporate family rating.

Moody's database of corporate defaults covers over 3,600 long-term bond defaults by issuers both rated and non-rated by Moody's. Additional data sources, such as Lehman Brothers index data, supplemented Moody's proprietary data in the construction of the aggregate dollar volume-weighted default rates. Defaulted bond pricing data was derived from Bloomberg, Reuters, and TRACE. The majority of these market quotes represent an actual bid on the debt instrument, although no trade may have occurred at that price. Over the 1982-2009 period, the dataset consists includes post-default prices for approximately 3,000 defaulted instruments issued by over 1,400 defaulting corporations. Moody's makes the 1970-2009 credit rating, default, and recovery rate data used in this study available through its Default Risk Service (DRS) database.

<sup>12</sup> For a more detailed discussion of rating accuracy metrics see Moody's Global Credit Research "[Measuring the Performance of Corporate Bond Ratings](#)", November 2006

<sup>13</sup> The accuracy ratio possesses the same information about discriminatory power as the area under the receiver-operator characteristics curve (AROC) and the Gini coefficient. Each measure quantifies rank rather than scale.
